GUIDE : MR. JEEVA. D, AP/IT

Abstract:

- ▶ Electronic voting systems have gained attention as a replacement for traditional paper-based elections; however, issues such as vote tampering, lack of transparency, and centralized control continue to raise serious concerns.
- ▶ To address these challenges, this project proposes a Blockchain-Based Secure Electronic Voting System using smart contracts. Blockchain technology provides decentralization, immutability, and transparency, ensuring that votes once recorded cannot be altered or deleted.
- ▶ In the proposed system, voter registration, vote casting, and result computation are managed through smart contracts deployed on a blockchain network.
- ▶ Each vote is securely recorded as a transaction, eliminating the need for a trusted third party. The system is implemented using Solidity for smart contracts, Node.js for backend services, and a web-based user interface for interaction.
- ▶ This approach improves trust, security, and auditability in electronic voting while maintaining system simplicity for academic and real-world adaptability.

Introduction

- ▶ Elections play a crucial role in democratic systems, requiring high levels of trust, accuracy, and transparency. Traditional voting methods, including paper ballots and centralized electronic voting machines, are vulnerable to manipulation, human error, and lack of verifiability. With the increasing digitization of government services, the demand for a secure and transparent electronic voting solution has become more significant.
- ▶ Blockchain technology, originally introduced for cryptocurrencies, has emerged as a powerful platform for secure record management due to its decentralized and immutable nature.
- ▶ This project explores the application of blockchain technology in the electronic voting domain. By leveraging smart contracts, the proposed system ensures that voter registration, vote casting, and result declaration follow predefined rules without human intervention.
- ▶ Each vote is cryptographically secured and permanently recorded on the blockchain, making unauthorized modifications practically impossible. The system aims to demonstrate how blockchain can enhance electoral transparency and trust while reducing dependency on centralized authorities.

Problem Statement:

- ▶ Existing electronic voting systems lack transparency and verifiability for voters.
- ▶ Voters cannot independently verify whether their votes are recorded correctly.
- ▶ Centralized databases are vulnerable to cyber-attacks and unauthorized modifications.
- ▶ Manual verification and audit processes are time-consuming and error-prone.
- ▶ There is a need for a secure, transparent, and verifiable voting system that minimizes human intervention.
- ▶ The challenge is to design a system that ensures one-person-one-vote while preserving data integrity.

OBJECTIVE :

- ▶ To design a secure and transparent electronic voting system using blockchain technology.
- ▶ To prevent vote tampering and duplicate voting using smart contracts.
- ▶ To enable verifiable and immutable vote storage.
- ▶ To reduce reliance on centralized election authorities.
- ▶ To provide a simple and user-friendly interface for voters.
- ▶ To demonstrate a real-world application of blockchain in governance systems.

Existing System

- ▶ Centralized electronic voting infrastructure.
- ▶ Election data stored in traditional databases.
- ▶ Vote counting and result generation controlled by authorities.
- ▶ Limited transparency for voters.
- ▶ Manual audits required to verify results.

Disadvantage

- ▶ Single point of failure.
- ▶ Susceptible to hacking and data manipulation.
- ▶ Lack of voter trust and transparency.
- ▶ Difficult to audit independently.
- ▶ High operational and verification costs.

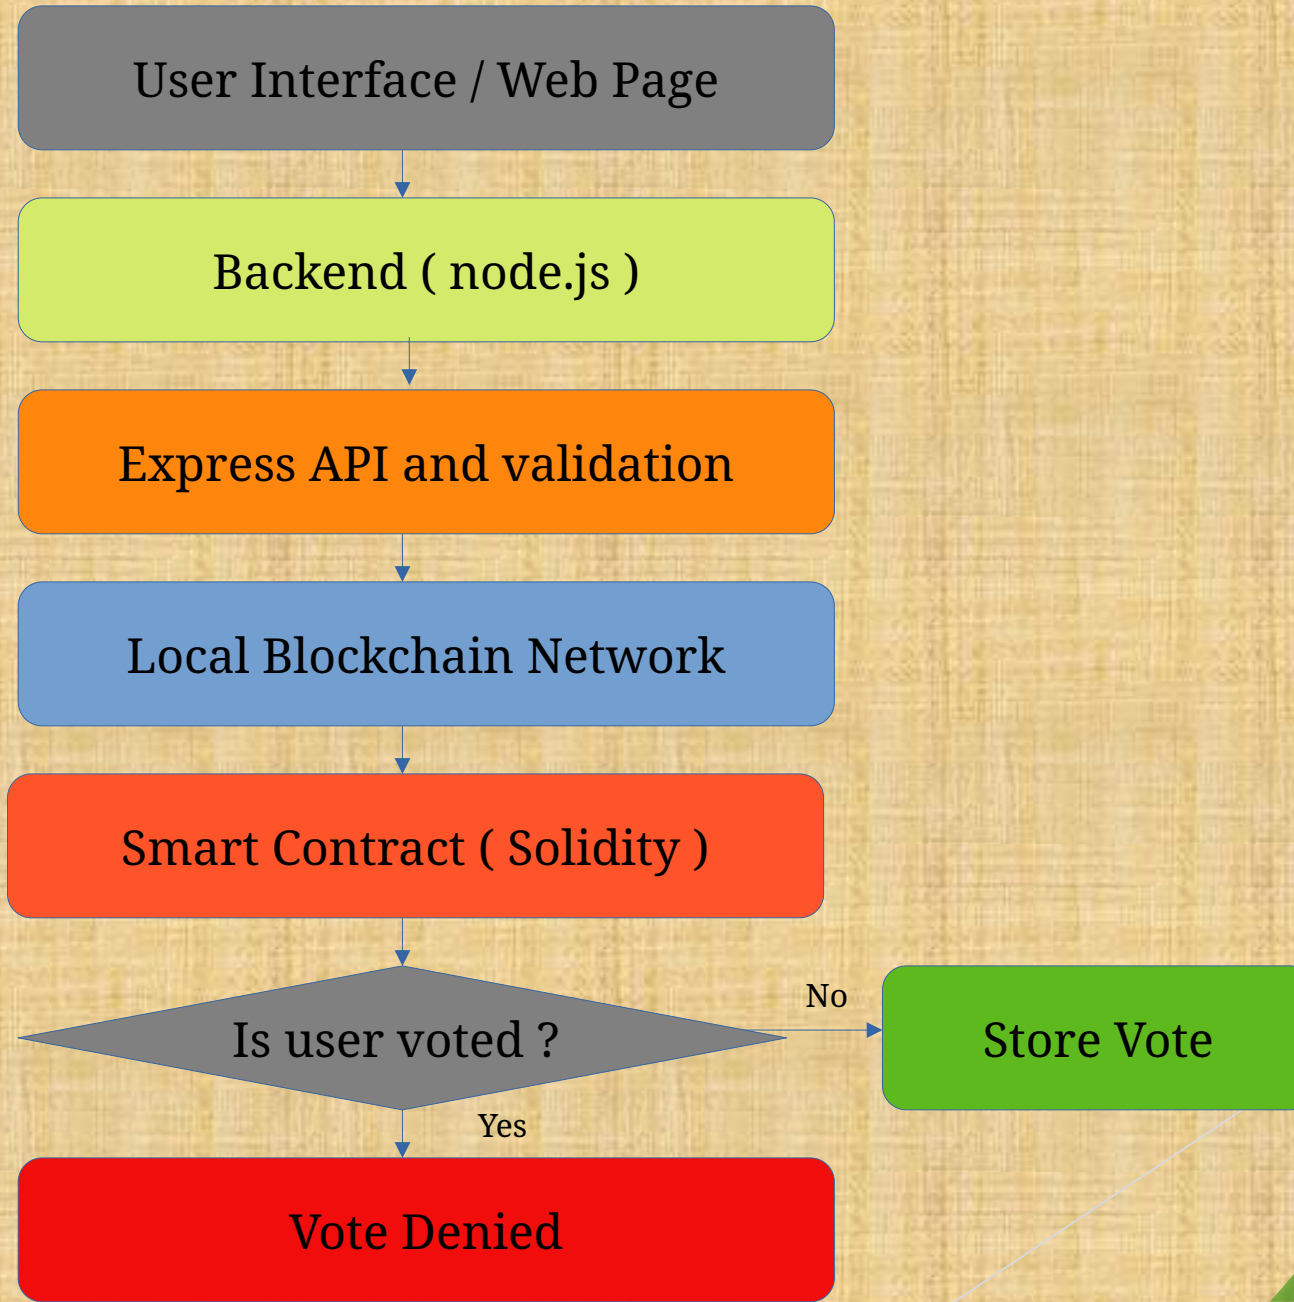

PROPOSED SYSTEM :

- ▶ Blockchain-based decentralized voting system.
- ▶ Smart contracts manage voter registration and voting logic.
- ▶ Votes stored on blockchain ensuring immutability.
- ▶ Transparent result computation.
- ▶ Automated enforcement of election rules.

Advantage

- ▶ No single point of failure.
- ▶ Tamper-proof and immutable vote records.
- ▶ Improved transparency and trust.
- ▶ Reduced manual verification.
- ▶ High security through cryptographic techniques.

SYSTEM ARCHITECTURE /FLOW DIAGRAM :

MODULES :

- ▶ User Interface Module
- ▶ Voter Registration Module
- ▶ Voting Module
- ▶ Vote Verification Module
- ▶ Result Management Module

MODULE 1: User Interface Module

- ▶ Purpose: Provide a secure, intuitive front-end for all users (voters, admins, auditors).
- ▶ Key Responsibilities:
 - Present registration, voting, and result views clearly.
 - Validate input before sending data to backend / blockchain.
 - Handle authentication flows and user feedback (errors, confirmations).
- ▶ Key Features:
 - Responsive design for desktop and mobile.
 - Multi-language support (if in scope).
 - Accessibility-compliant layouts and controls.
- ▶ Technology Stack :
 - Web: Javascript, Nodejs
 - Styling: CSS / TailwindCSS .
 - Integration: Express, Ganache.

MODULE 2: Voter Registration Module

- ▶ Purpose: Onboard eligible voters and ensure only valid identities can cast votes.
- ▶ Key Responsibilities:
 - Capture voter identity and eligibility details securely.
 - Interface with external ID/registry systems (if applicable).
 - Issue unique voter credentials / keys linked to blockchain identity.
- ▶ Core Flows:
 - New voter registration and verification.
 - Updating voter details (within configured rules).
 - De-duplication and fraud detection checks.
- ▶ Security & Compliance:
 - KYC / legal requirements (jurisdiction-specific).
 - Encryption of PII, strict access controls, and audit logs

MODULE 3: Voting Module

- ▶ Purpose: Enable voters to cast ballots securely and anonymously via the blockchain.
- ▶ Key Responsibilities:
 - Present live ballots and options to authenticated, eligible voters.
 - Validate voter eligibility and “one person, one vote” rules.
 - Submit votes as blockchain transactions with end-to-end integrity.
- ▶ Core Flows:
 - Ballot selection and confirmation (review screen).
 - Vote encryption and signing with voter keys.
 - Handling network / transaction failures and retries.
- ▶ Quality & Security:
 - Strong cryptography for ballot secrecy.
 - Protection against double-voting, replay, and tampering.

CONCLUSION

- ▶ The proposed blockchain-based voting system addresses major drawbacks of traditional electronic voting.
- ▶ Decentralization eliminates single points of failure and increases system reliability.
- ▶ Smart contracts enforce election rules automatically without human intervention.
- ▶ The system enhances transparency, security, and voter trust.
- ▶ The prototype demonstrates the practical feasibility of blockchain in electronic voting.
- ▶ This work lays the foundation for future large-scale and national-level implementations.

THANK YOU !
